Breast cancer is the most common malignancy in women. Although it is not classified as a hereditary cancer, women who carry mutations in the BRCA1 gene are at high risk of developing breast cancer. Here we review current evidence about the cellular and molecular pathways in which BRCA1 participates, as well as the analysis of alterations in the BRCA1 protein found in hereditary breast cancers. BRCA1 has been classified as a ubiquitously expressed protein, participating in a wide variety of biological processes. While some of its functions may be related to the maintenance of genome integrity, BRCA1 is also involved in the regulation of cellular proliferation and senescence. In addition, recent evidence has shown that this protein may also play a role in the control of gene transcription and, more interestingly, has been linked to the alternative splicing of some genes. The analysis of BRCA1 protein expression in different tissues has shown that it may play different roles depending on the cellular context, indicating that these functions are not just overlapping but are independent of each other. This functional diversity, which has been recently termed the 'BRCAness' phenotype, may help to explain why women who carry mutations in the BRCA1 gene are at higher risk of developing breast and ovarian cancers, but only a subset of the women with a BRCA1 germline mutation develop breast and ovarian cancers.I have lived here for 2 years and I've never felt safer than I do now.
